

Beyond the Fossil City: Towards low Carbon Transport and Green Growth

Sustainable Urban Transport Technical Document # 6

By Daniel BONGARDT, Manfred BREITHAUPT and Felix CREUTZIG

Abstract

Transport is a fast growing sector. A steadily increasing motorisation along with urbanisation is a trend that can be observed in most developing countries. This and the oil dependence of the transport sector lead to considerable growth rates of carbon emissions. Actions to stop this trend are urgently needed. This paper shows how national and/or urban low-carbon transportation policies could help countries to achieve a smart, sustainable economic growth while at the same time stabilizing and later reducing transport emissions. Sustainable Development Policies and Measures in the transport sector include a variety of co-benefits, *e.g.* reduced air pollution, social equity and economic development. In the context of the global economic crisis such measures promote economic growth, social stability and can also be implemented at reasonable costs.

This paper was initially published as a background paper to the Environmentally Sustainable Transport Forum (EST) 2010 organised by UNCRD in Bangkok on 23–25 August 2010 (see <http://www.uncrd.or.jp/env/5th-regional-est-forum/index.htm>).

1. The challenge

While transportation is crucial to the economy and individuals, as a sector it is also a significant source of greenhouse gas (GHG) emissions and can affect human welfare negatively. Transport is currently responsible for 13 % of greenhouse gas emissions worldwide and 23 % of global carbon dioxide emissions (CO₂) from fuel combustion are transport related (International Energy Agency, 2008). Transport related CO₂ emissions are expected to increase by 57 % worldwide in the period 2005 – 2030, much more than emissions from any other sector. But there is consensus in science and politics that global GHG emissions have to be reduced by more than 80 % by 2050 from 1990 levels in order to avoid catastrophic global warming. When contrasting the current growth rate of transport-related emissions with aspired reduction targets, it is obvious, that the transport sector needs to start contributing to mitigation efforts now.

Between 1990 and 2005, transport energy consumption increased by 37 %, and was the fastest growing end-use sector. The associated CO₂ emissions rose broadly in line with this increased energy use to reach 5.3 Gt. Within transportation, road transport is by far the largest energy user and accounted for 89 % of total transport energy use in 2005 (IEA, 2008). Road transport is also the main contributor to increased transport energy use. While the energy consumption of non-road modes increased by 13 % between 1990 and 2005, the energy use of road transport rose by 41 %. In Figure 1 the increasing amount of the different transport sub-sectors over the past years (1971–2005) is presented.

Figure 1
World transport energy use by mode, 1971–2006

Source: (IEA, 2009)

In the USA, a world region with a high dependency on automobiles, the transportation sector directly accounted for about 30 % of total GHG emissions in 2006. Just following the electricity generation (34 %) it became the second largest source of GHG emissions. Around 60 % of global road transport emissions currently originate from North America and Western Europe.

In Asian countries GHG emissions from the transport sector constitute a smaller proportion of national total emissions. For example, in China 7 % of energy-related CO₂ emissions were from transport in 2007 (IEA 2009). Trends in energy use by transport mode vary significantly amongst countries and regions. On average, the growth in non-OECD countries (+55 %) was faster than in OECD countries (+30 %). The large increase in non-OECD countries is in part attributable to the rapid economic growth of several major countries, creating

- increased personal disposable incomes,
- higher vehicle ownership, and
- increased need for freight transportation.

For instance, China tripled its energy consumption in the transport sector between 1990 and 2005 and is now just behind the USA and Europe on the third rank in terms of transport related GHG emissions (IEA, 2008). Hence, imminent global warming requires action in

developed and developing countries alike. In contrast, in Germany, with very high fuel prices, GHG emissions from transport first stabilised and have been slightly falling year by year over the past 8 years.

To meet long-term climate targets, developed countries should reduce greenhouse gas emissions by 80 to 95 % until 2050 compared to 2000 levels. But also non-OECD countries need to reduce their GHG emissions significantly by 2050. It is also clear that OECD countries have a bigger responsibility and need to support the developing world in this undertaking.

Low-carbon transport is confronted with a number of barriers that need to be encountered by strategic action. These barriers are:

1. ***Time-lag between decisions and effects***: Some measures require a long-term approach that only takes effect when continuity in political decision-making is achieved.
2. ***Cross-cutting*** nature of transport: Many decisions in other sectors influence transport demand. Integrated decision-making is needed.
3. ***Fragmented*** target group: Everybody and all social groups demand on mobility. The sources of emissions are rather small, so there is a need to bundle measures.

Current models of development promote the automobile as a symbol of well-being and societal advance. Unfortunately, this so-called ‘American way of life’ is doomed to fail in times of increasing resource and oil scarcity. This is especially true for cities that have never evolved around the automobile. In fact, such an automobile-centred development is outdated and can be superseded by a modern society that is sustainable in the environmental but also in the economic sense and promotes social stability. At the moment, many industrialised countries struggle to overcome the car-dependency and face strong difficulties to turn back, while an increasing number of industrialised cities are in the process of breaking the trend. In light of this experience, it becomes even more important for developing countries to not end up in the same trap but choose a more sustainable path – not only to combat climate change rather to develop a reliable and convenient transport system, and to improve the local environment.

2. Vision and opportunities

Low-carbon transportation is not a burden but increases liveability and well-being, providing many other advantages as well. Low-carbon strategies or roadmaps are therefore supporting an avenue towards a modern, sustainable and stable society.

Figure 2
*Freiburg, Germany,
is an example of
a liveable city.*

A low-carbon transportation infrastructure that follows the principles of sustainable development not only mitigates climate change but also realises the following co-benefits:

- Increase of **energy security** as less oil needs to be imported. Resource conflicts can be avoided and transport users won't have to suffer from fuel price shocks;
- Reduction of traffic congestion, and consequently air pollution and noise are reduced, having a positive impact on the **environment** and **human health**;
- **Reduction of land demand** by preventing urban sprawl and preferring semi-dense mixed-use neighbourhoods;
- Provision of visibility and acknowledgement of cities that demonstrate leadership: sustainable and modern low-carbon transportation systems increase the **competiveness and attractiveness** of cities and create incentives towards top companies, highly qualified workers and employees to settle into the country (see Mercer Liveability Index);
- Pending on future climate change agreements – cities and countries that achieve mitigation beyond baseline scenarios gain access to emission certificates and carbon related **funding** schemes;

Last but not least, there is a **political co-benefit**: Citizens will recognise that convenient and high quality public transport and non-motorised transport infrastructure saves money and time. In London the popular mayor Ken Livingston was elected mainly because of his innovative transport policies.

Important abatement policies such as decisions on land-use development do not necessarily require high investments. Technological fuel-based mitigation solutions have been reported to cost between US\$ 150 to US\$ 3 500/tonne CO₂, whereas modal share improvements only cause emission reduction costs between US\$ 14 and US\$ 66/tonne CO₂ (Wright and Fulton, 2005). In this regard, low-carbon transport measures and efficient transport services are a considerable opportunity and safe-guard for the future (IEA, 2009).

Elements of a vision for a low carbon transport system are:

- Dense but green and mixed used cities that allow white collar jobs, shopping and leisure facilities close to people’s living quarters;
- Modern, high quality links between the centres and good integration of long-distance hubs with local transportation;
- High quality alternatives to individual car-use, especially efficient public transport and good non-motorised transport infrastructure and its proper integration;
- Efficient, inter-modal freight transport and smart urban logistics that also includes clean vehicles;
- Advanced technologies such as electric/gasoline hybrid engines, alternative fuels or even electric motorbikes and cars.

There is a high need to manage transport demand in order to make the best and most cost-efficient use out of valuable land and infrastructure. Examples like Zurich, Vienna, London, Paris, New York, Hong Kong, Singapore and many others demonstrate that economic success is directly linked to advanced sustainable transport systems. Moreover, a higher share of alternative transport modes is directly related to less pollution from cars and less CO₂ emissions. This has a positive impact on air quality and reduces the contribution of transport related emissions to climate change.

In Table 1 the modal share for public transport and non-motorised transport means, as well as the CO₂ emissions per capita per year for different cities, is presented. These figures show how a high share of alternative transport modes is directly related to less CO₂ emissions.

Table 1: CO₂ emissions from passenger transport vs. modal split in selected cities

	% of public transport, walking and cycling	CO ₂ emissions (kg per capita per year)
Houston	5 %	5'690 kg
Montreal	26 %	1'930 kg
Madrid	49 %	1'050 kg
London	50 %	1'050 kg
Paris	54 %	950 kg
Berlin	61 %	774 kg
Tokyo	68 %	818 kg
Hongkong	89 %	378 kg

Instruments and tools are available but political action and good management is required on local, regional and national level. Particularly, instead of focusing on specific technological options, a systemic approach can facilitate enduring transport systems and realise several co-benefits.

In fact, many cities demonstrate that a well designed public transport system and non-motorised transport infrastructure are important tools to trigger economic success. In the next chapter, strategic approaches are developed that enable decision-makers to go forward. This includes the development of policy packages and roadmaps for implementing the packages.

3. Towards Low-Carbon Transport: Avoid/Reduce – Shift – Improve

To achieve significant emission reductions and realise a sustainable and attractive infrastructure, novel and innovative approaches are required. In general, greenhouse gas emissions in the transport sector can be reduced through a number of measures and approaches which will be discussed below.

Figure 4
Low-carbon transport modes in Hangzhou, China.

Photo: Karl Fjellstrom, 2006

Ambitious emission reduction targets can best be reached when all factors simultaneously contribute to mitigation. According to current projections, the carbon content will be reduced and energy efficiency will improve only marginally, while travel demand further explodes in developing countries. A low-carbon transportation system needs more than a piecemeal approach and requires improvement in all dimensions – travel demand, mode choice, and technology – simultaneously to quickly gain traction.

Figure 5
Infrastructure for plug-in vehicles in San Francisco.

Photo: Felix Kramer, 2009

A main framework for strategic action is the so-called Avoid/Reduce-Shift-Improve approach (GTZ, 2007), where infrastructure is provided in such a way that:

- Future travel demand is reduced or avoided;
- Travel is shifted to more economic and environmentally-friendly modes;
- Technological measures improve the vehicle fleet and fuels.

Such a coherent approach has the potential to contribute to emission reductions beyond current expectations. It also would transcend current piecemeal measures such as introducing a few but very expensive hydrogen busses. Instead, sector-wide policies and city-wide schemes can achieve reasonable scales.

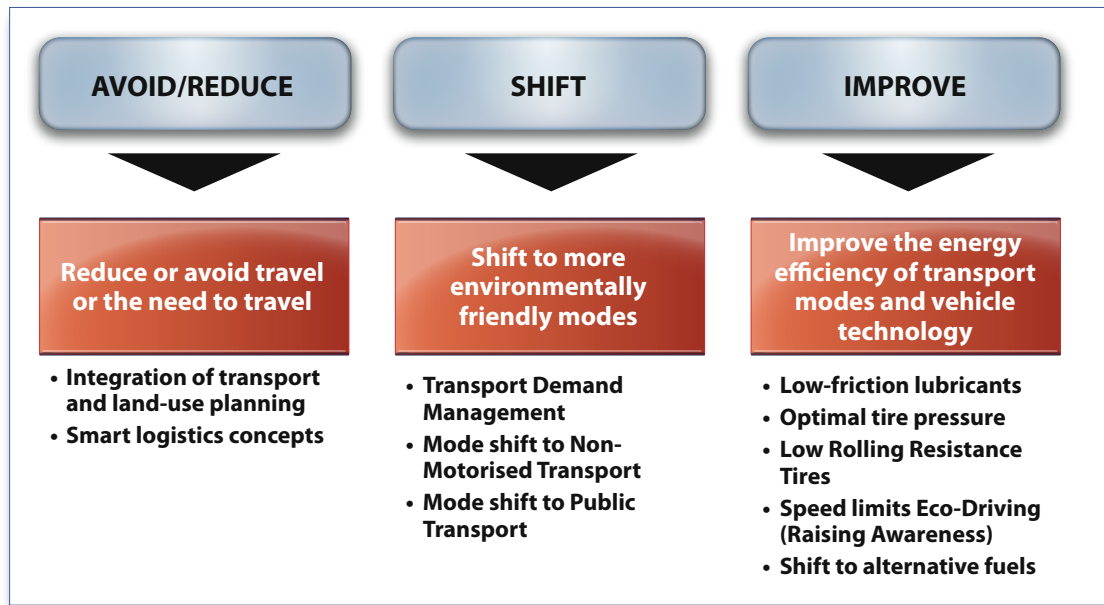

Figure 6
*The GIZ approach:
 Avoid/Reduce
 –Shift–Improve.*
 Source: GIZ

Avoid/Reduce-Shift-Improve is an important and innovative agenda for OECD and non-OECD countries. Developing countries often have the opportunity to develop sustainable infrastructure in growing cities, and to maintain high shares of traditional and low-carbon modes, while at the same time “leapfrog” to environmentally-friendly technologies. In contrast to particularly North America, transport infrastructure is often newly constructed and car ownership is in many cases relatively low. By enabling a less car-dependant mobility, developing countries can successfully avoid the high-level of car-dependency and carbon-lock-in syndromes in politics and society.

Figure 7

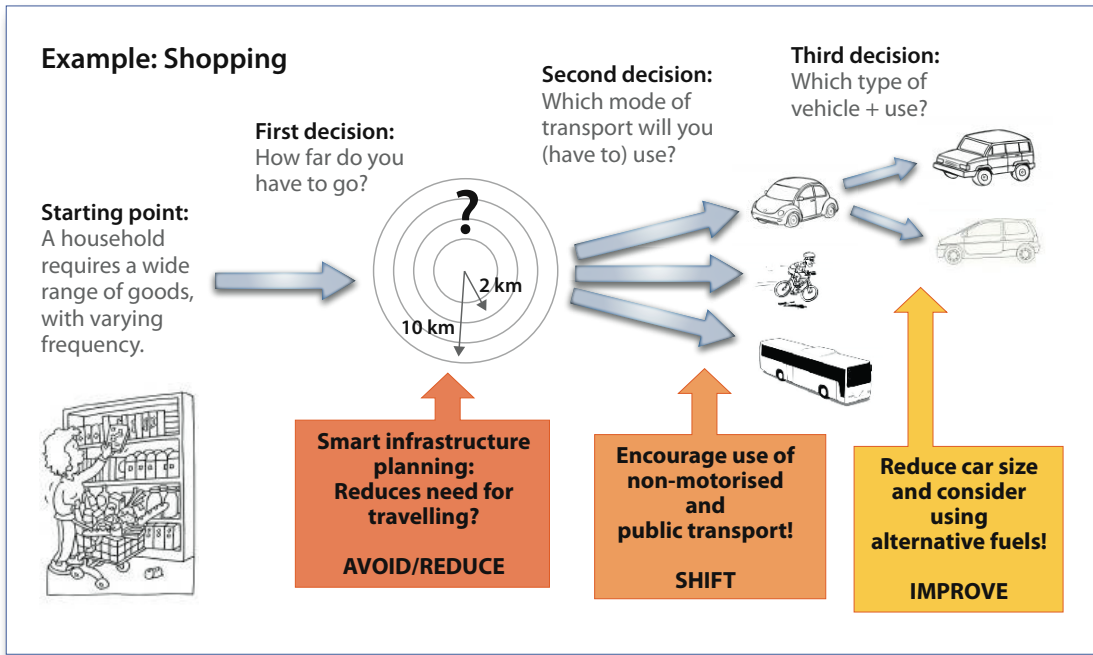

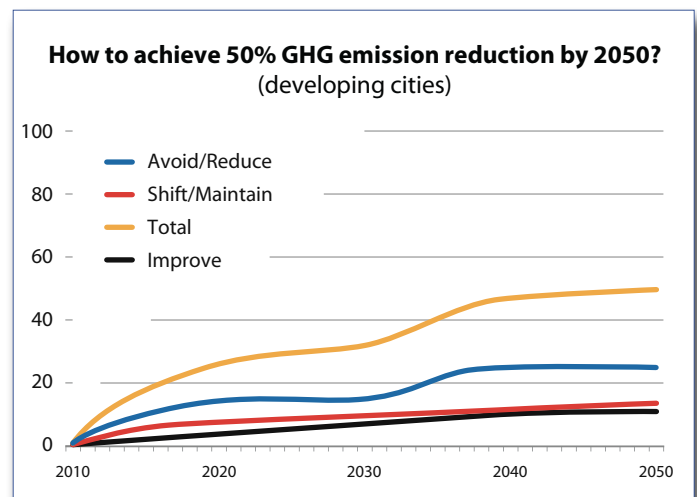

Figure 8
Traffic generation and carbon emissions: what aspects should we concentrate on?
 Source: GIZ

For changing the paradigm there are three relevant time-frames.

- A short term time-frame is related to immediate behavioural changes. For example, one can economise on the number of trips and do most errands in one round. Such behavioural changes are mostly induced by price signals and informative measures.
- A medium term time-frame addresses vehicle technology. It is determined by the life span of automobiles, the speed of phase-in and the percentage of 'efficient' cars bought in a specific year. Altogether, this time-span is approximately 10–15 years.
- A long time-scale is determined by infrastructure decisions. For example, peripheral land can be developed into low-density suburbia, or clearly structured with peri-centres, semi-autonomous services, shopping infrastructures and mass rapid transit systems. In suburban areas, inhabitants are highly dependent on cars. Cities can be car-friendly with huge arteries and abundant parking space, or they can be pedestrian and bicycle friendly with walkable neighbourhoods. Mostly, both designs are not compatible with each other. This time-scale is dominated by a) political decisions to promote car-dependent or non-motorised-friendly infrastructures and b) relocation decisions by citizens (both are mutually dependent on each other).

Figures 9a, 9b
The potential for emissions reduction with the Avoid-Shift-Improve Approach.

In the long run, infrastructure decisions are particularly important since most expected emissions growth from road transportation in the business-as-usual scenario comes from additional demand created in developing countries. Particularly in these countries many investment decisions on road infrastructure and land-use development are currently taking place. Even with a substantial emphasis on fuel-efficient cars, infrastructure decision can lock China, India and other countries into a fragile situation.

4. Policy packages for sustainable development

In many cases, policy packages or sets of measures produce considerable synergies that lead to an overall effect that goes beyond the sum of their singular impacts. This is important especially when it comes to sustainable development in the transport sector. Sustainable transport policies consist not only of a set of measures but also target a coherent set of goals. Climate change is crucial for many Asian cities, as their Himalayan water supplies melt away or they face the danger of rising sea-levels, floods or droughts. However, in many cities, climate change is not the most relevant issue in the short-term.

Low-carbon policies must be integrated with goals that are relevant for sustainable development within the city. For some cities, clean air will be the main target. For other cities, congestion relief and more reliable transport, but also higher accessibility for all parts of the population may be crucial. A sustainable transport system may also attract business and tourists that value high life quality. Individual policy instruments were introduced in the “Transport and Climate Change” module (GTZ, 2007) but also in other GIZ modules such as Transport Demand Management.

In the following paragraphs, we discuss policy packages: a set of instruments that evolve synergistically when deployed together on two levels: the national arena and the urban scale. The urban perspective is of particular interest, as many development decisions on infrastructure that create or avoid additional car-travel demand are made in cities. However, there is a need that urban policies are designed in coherence with national policies that (a) influence technology development and diffusion, (b) enable pricing and competitiveness of low-carbon modes and last but not least (c) improve long distance freight and passenger transport. Furthermore, the national level is important to assist local decision-makers through investment programmes or capacity development.

4.1 The National Policy Packages

National governments can implement direct measures and enable local low-carbon policies. The spectrum of possible policies is displayed in Table 2 and structured along three policy packages. They are built on each other and demonstrate a step by step development of a sustainable transport policy. However, it must be noted that each single policy needs to evolve over time and should be adapted to the stage of development; *e.g.* fuel efficiency standards need to get tighter over time, and investment programmes for urban transport need to be upscaled or adapted to the most recent approaches.

It is not easy to quantify the impact of each of these measures as they are interdependent and different time-frames are involved. In general and as a hint, we assume that by each stage and upgrade of the policy package countries are able to cut carbon emissions by 20–40 % against business as usual scenario within a timeframe of 40 years. This sums up to savings of 50–80 % until 2050 for those implementing an advanced reduction package.

While the “Basic Package” should be implemented in all countries – also in the “least developed countries” – as soon as possible, the advanced package is an intermediate step towards the deluxe package. As it takes a step by step approach, leaders can already outline the vision of a low or zero carbon city while still being in an initial phase. All packages include co-benefits as described above.

The idea of the ***basic package*** is to remove the factors that trigger car-use and start the development of low carbon infrastructure so that shifting to the environmentally friendly and sustainable modes and practices meets also economically interests. The earmarking of subsidy savings or taxes for investments in alternative modes makes the package communicable, *i.e.* enables decision-makers to explain it to the public.

Table 2: National Level Policies and Packages

Policies	Basic Package <i>(implemented in all countries also in least developed countries)</i>	Advanced <i>(for advanced countries that face rapid development of car-ownership)</i>	Deluxe Package <i>(for most developed countries with high levels of motorisation)</i>
1. Removal of fuel subsidies Remove incentives for non-sustainable transport modes.			
2. Fuel taxation above European minimum taxation level. Give incentives to travel less, use low carbon modes and purchase fuel efficient vehicles.			
3. Low carbon long distance infrastructure Earmark a considerable share of the transport investments in low carbon modes.			
4. Efficiency standards Regulate car producers and correct market failures.			
5. Removal of further car-oriented subsidies <i>e.g.</i> for business cars in order to remove barriers for sustainable transport modes; replace with job-tickets.			
6. Incentive Programme for municipalities to set up TDM, public transport and NMT investments and integrated land-use and transport plans.			
7. Vehicle registration tax/ license auctioning <i>e.g.</i> taxing fuel inefficiency or weight.			
8. Low-carbon fuel standards Incentivizing low carbon fuels, <i>e.g.</i> electric cars.			
9. Research, Development and Demonstration For fuel efficient cars, electric bikes, busses and smart public transit.			

Rapidly developing countries that face a strong increase in car-ownership, need to tackle the growing emissions also by involving the vehicle manufacturers. In the *advanced package* this feature is added through fuel economy standards. Furthermore, as motorisation and urbanisation take place simultaneously, cities need to be supported by the national level. An incentive program for municipalities like the Indian JNNURM helps in facing this challenge and enables innovation on local level.

For most developed countries with high levels of motorisation the *deluxe package* allows further reduction. This includes high taxation for fuels as well as vehicles and investments in new technology and research. However, countries have to make sure that measures, described in the other packages, are effectively implemented, as each package builds on the previous steps.

In the following paragraphs, three key measures to reduce carbon emissions are presented in more detail: Fuel prices, fuel economy standards and urban transport policies. For the description of further approaches the Module 5e: *Transport and Climate Change* gives further insights.

4.1.1 Fuel prices

An increase in fuel prices has the most immediate effect on car use. This can be seen for, *e.g.* in Indonesia, where even low income cities are characterised by a very low public transport share. In some Indonesian and Malaysian cities public mode share is below 5%. Fuel subsidies are contra productive and should be discontinued. Appropriate fuel pricing is an effective energy conservation and emission reduction strategy. Implementation costs are minimal, since most jurisdictions already collect fuel taxes. The petroleum industry argues that an increase in fuel taxes harms the economy, a claim that cannot be substantiated.

Figure 10
*Petrol station in
Ho-Chi-Minh-City.*

Photo: Karl Fjellstrom, 2004

These costs are primarily economic transfers within the economy, since increased costs to motorists are offset by increased revenues or reductions in other taxes. Higher energy taxes reduce the dependency of petroleum-consuming nations on petroleum producers. They also motivate businesses to become less transport intensive, more efficient and increase innovation and overall productivity, while low energy prices encourage wasteful use of resources, which is overall harmful to the economy. Some principles of increasing fuel prices are (GTZ, 2009; Durning and Baumann, 1998):

- Fuel tax revenues should be used to improve transportation in general, rather than just roads, so that travellers have more fuel efficient accessibility options;
- Revenues generated by the new tax should be returned to individuals and businesses through reductions in other taxes. That is, taxes should shift from “goods” to “bads”;
- Tax shifts should be gradual and predictable, *e.g.* 10 % annually, so consumers and businesses can take higher energy costs into account when making long-term decisions, such as vehicle purchases and building locations;
- Tax reductions and rebates should be structured to favour lower-income workers and other disadvantaged groups;
- Taxes should be applied to the full category of harmful goods, with minimum exemptions, in order to make the tax credible;
- Crucial is an open and appropriate communication policy to let the public understand the underlying principles and reasoning for such policies.

The first step is to cut subsidies that bring pump fuel prices below crude oil prices. This is the challenge currently facing countries such as Egypt and Yemen. Certain countries can serve as important models for a region. In the past year, Morocco, Tunisia and Ghana have reached reasonable fuel price levels. On the contrary, Indonesia continues to subsidize fuel, with a range of negative effects, including the indirect promotion of individual transport modes, especially of motorbikes, and hence a low public transport mode share.

4.1.2 Fuel economy standards

In addition to price signals, a main instrument to force production of fuel-efficient cars is fuel efficiency or fuel economy standards for car producers. This policy mechanism usually specifies, through a regulatory or political process, the average per-kilometre fuel consumption of new vehicles sold in a given year. Fuel-economy standards are intended to induce innovation in vehicle technologies to curb or reduce oil consumption. Fuel-efficiency standards are meanwhile the most effective climate policy tool in the USA, while the understated fuel taxes are not supporting shifts towards more sustainable transport modes. As car drivers often do not consider fuel consumption when they purchase automobiles, obligatory standards address a crucial market failure. As a disadvantage, they do not influence driving behaviour, and might even induce additional driving (the so-called rebound effect) when no price signals are in place.

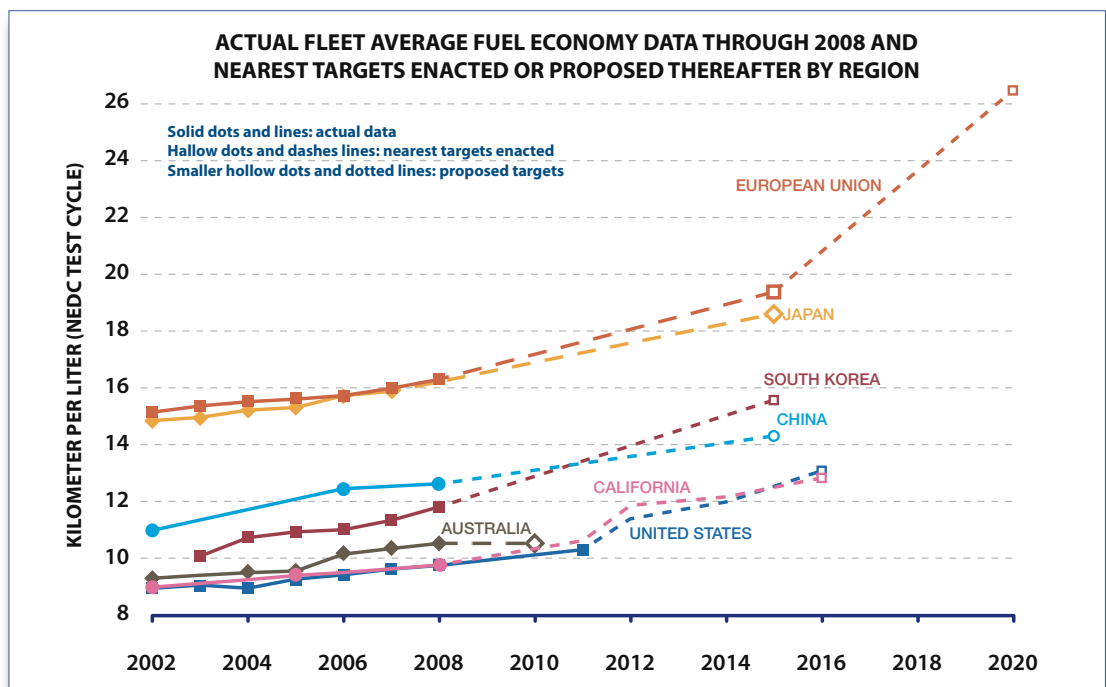

Figure 11
Energy efficiency
improvements and
future targets.
Source: ICCT

Governments can also act directly by taking their own measures. For example, they can incentivise public transit in their own ranks by *providing mobility lump sums* for government employees, instead of car benefits. This sets an example for all citizens and can also help capital cities such as Bangkok or Beijing in their drive towards sustainable transport systems. Governments can also choose to purchase highly fuel-efficient duty vehicles.

Figure 12
Energy efficiency technologies for cars.
Source: Axel Friedrich

4.1.3 Urban transport policies or programmes

A third key measure is *enabling local and urban authorities* to advance low-carbon transportation. This is especially important when it comes to investments in low carbon infrastructure. The major challenge that faces urban policy-makers is to finance a sustainable urban transport system and ensure sustainable funding in the long-term. By providing the necessary financial resources for investment and institutional building, the capacity to raise and manage funding at the local level can be build up and the fragmentation of responsibilities amongst the relevant (transport) authorities can be defeated (see GTZ Sourcebook Module 1f: *Financing Sustainable Urban Transport*).

Under this principle national transportation funds can be dedicated at a much larger scale to public transport, bicycle and pedestrian infrastructure. A sustainable urban transport policy or program systematically supports cities to invest in low carbon transport systems. Funding is usually related to some conditions, *e.g.* earmarked for specific measures or the preparation of a comprehensive integrated transport plan. India provides a good example for such initiatives (see Box 1).

4.2 The low-carbon city

The developing world's urban population will double by 2030 (UN, 2004). Most of the additional travel activity in the next decades, hence, will be produced in the growing cities of the developing world. The inertia of such a trajectory holds danger but also promise: If the current development continues towards car-dependency and concrete miles maximisation, GHG emissions will be fixed for half a century or longer. However, if an alternative low-carbon development gains traction, a fundamental lower emission trajectory can be achieved. As a basic

Box I

Jawaharlal Nehru National Urban Renewal Mission (JNNURM) in India

Rapid economic growth, coupled with a fast growing urban population, and urban sprawl has resulted in increased individual housing requirements, and an ever increasing demand for mobility in Indian cities. This has exerted huge pressure on the city's existing resources and made development patterns in the cities unsustainable. One financial instrument to improve the situation and to provide adequate infrastructure to the cities is the National Urban Renewal Mission (NURM). It provides a platform to coordinate significant financial support from the Central Government in urban infrastructure projects to selected cities in India, subject to the cities undertaking a set of institutional, structural, and fiscal reforms, necessary to improve their urban service delivery systems. Towards this, cities identified by the Mission are expected to formulate comprehensive City Development Plans (CDPs) for a period of 20–25 years, with 5 yearly updates, indicating policies, programmes and strategies, and financial plans. Based on the CDPs, more detailed project reports are to be developed with regard to undertakings in the sectors of land use, environment management and urban transport. Once this task is completed, the next steps are to initiate identified projects with funds from Central and State Government.

At inception of the National Urban Renewal Mission in December 2005, the total support of the Government was envisaged at Rs. 50 000 crores (USD 11.1 billion) with matching contribution from states and municipalities to an overall fund of around INR 100 000 crores (USD 22 billion). During 2008–2009 the commitment of the central assistance was enhanced by INR 16 500 crores (USD 3.7 billion) so that a total fund volume of INR 116 500 crores (USD 26 billion) was available.

The financial support for 112 transport and transport related projects currently amounts to USD 2 billion and constitutes a share of 23 % of all the 478 approved infrastructure projects.

Under urban transport, the cities are further expected to draw up Comprehensive Mobility Plans (CMPs) which detail out the city's transport policy objectives and how they will be implemented. Examples of sustainable urban mobility projects supported under the JNNURM ambit are the various Bus Rapid Transit System (BRTS) projects that are being initiated in Indian cities. BRTS proposals are in various stages of appraisal and implementation. BRTSs have been implemented successfully in few Indian cities which include Ahmedabad, Pune, Bhopal or Jaipur. Also, under the JNNURM programme, cities are now eligible to request grants in order to purchase buses for city bus operations. In this context, a total of 15 260 buses were sanctioned for 61 Mission cities across the country. All these buses are to be modern, low floor and semi low floor with various Intelligent Transport System features as in the Urban Bus specifications.

More information on the JNNURM guidelines can be found at: http://jnnurm.nic.in/nurmudweb/toolkit/guidelines_jnnurm-English.pdf

principle on city level, urban development planners should aim at *achieving density*: The aim must be to retain or achieve medium to high urban density profiles. This is a precondition for efficient and convenient accessibility by walking and cycling, and for making public transport profitable.

In the following three transport-related packages are presented that are – again – linked to the stage of development of a city (basic – advanced – deluxe). Each of these packages includes elements in eight different areas of activity. Ideally, policies shall cover each of the eight areas as managing demand requires an approach that optimises different parameters of the transport system. Thereby, it follows a “*Push and Pull Approach*” (see for details GTZ’s Manual for *Transportation Demand Management*, 2009). It is fundamental that a set of measures simultaneously:

- a) pushes transport users out of the car or gives incentives to prospective users not to buy a car and, at the same time
- b) pulls them to the low carbon modes public and non-motorised transport.

Figure 13
In Amsterdam, non-motorised transport has one of the highest modal shares among other European cities.

Cities can be extremely successful with focusing on public transport modes. Zurich, Vienna, Hong Kong and Singapore all invested heavily in public transport, which led to increasing per capita transit trips. This was accompanied by substantial income increases. In fact, promoting the environmentally friendly modes can increase the attractiveness of a city considerably, and attract both companies and well-qualified employees. Singapore, for example, has made city-wide transport to a high priority in land-use planning. In the 70s, Singapore was advised to only upgrade the bus system, but the government nonetheless pushed for a much more expensive rail system. Rail modes are rapid and comfortable but less flexible. Buses and mini-buses add local flexibility to the overall system and have the advantage of more speed and comfort, which makes them more competitive to cars. While many Asian cities from Manila to Urumqi invest heavily in highways and motorised transport, the high density of these cities makes them ideal candidates to build an efficient, economically lucrative public transport system from which environment and society can profit.

The following diagram illustrates how public transport facilities have to be dramatically improved, that is to say, push measures are to be strictly applied in order to discourage car use in inner-cities.

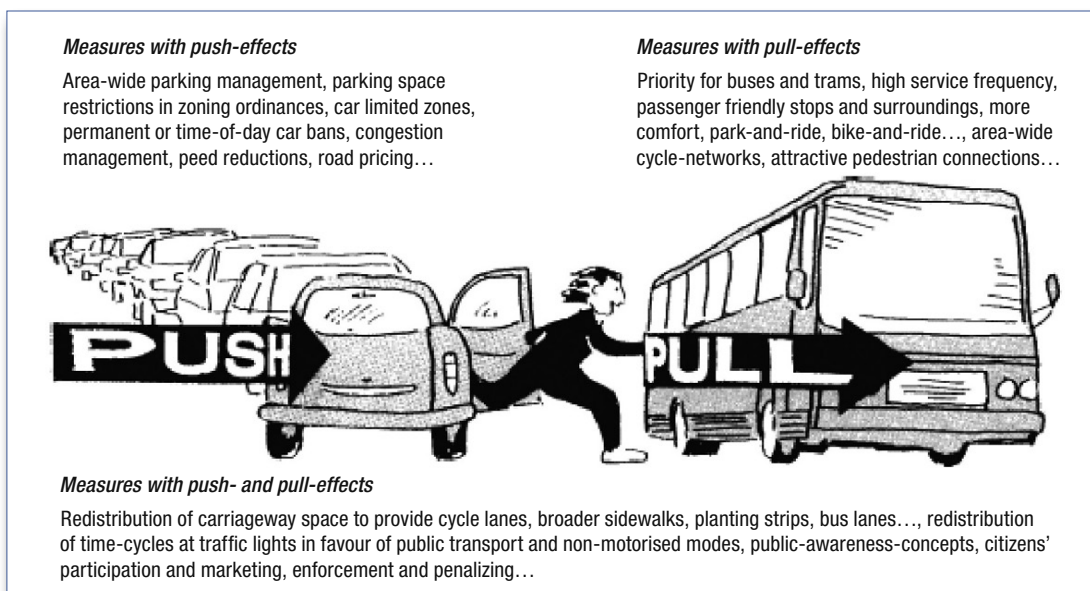

Figure 14
The Push and Pull approach.

Road space in most cases cannot be extended in cities, and it also makes no sense, since induced traffic will quickly full up additional space. Therefore the decision is vital on how to best use existing road space. In some advanced cities road space in some inner city streets is only given to Mass Transit, cycling and walking.

Figure 16 summarises the interrelation of activities in urban transport systems: car restrictions and NMT, high

quality public transit and mixed-used high density urban development. Each element on its own can contribute only little to a sustainable transport path, all together they can realise considerable synergies and plant the seeds for a low-carbon future.

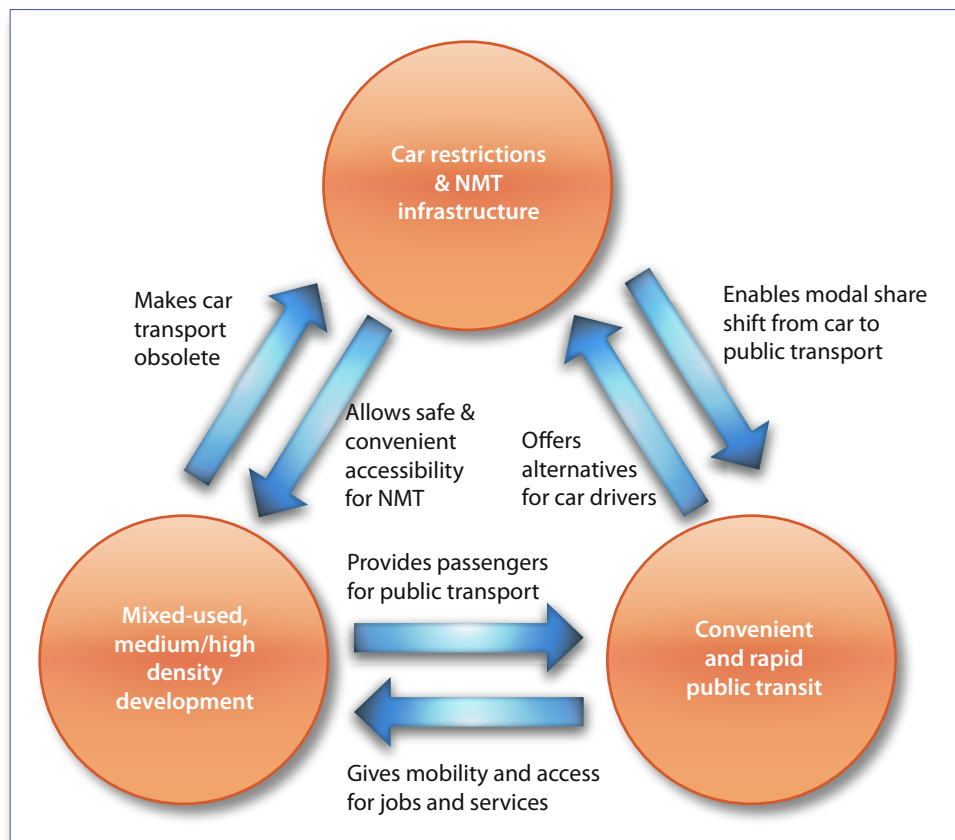

Figure 16
Three elements of low-carbon urban development.

Clearly, it is not enough to just have good ideas, they also must be implemented. Specific integrated planning agencies can foster sustainable transport concepts, whereas others constitute barriers. If institutions are fragmented and work in ignorance of each other and without a coherent perspective, no integrated, high efficient development approach can be achieved. Good examples can be found in Singapore, Curitiba, meanwhile in Seoul, and in German agglomerations.

And it is possible! Even in previously notorious car based cities such as Athen a change towards a higher use of non-car based transport was achieved.

Integrated land-use and transportation planning: bus-centred linear development in Curitiba

The most consistent approach, and by now state-of-the art in progressive cities, is to **integrate land-use and transportation planning** to achieve a low-carbon infrastructure, reduce travel distance and travel time and increase accessibility to jobs, shops and leisure facilities. The bottom-line is that new mixed-use, high density developments must be close to public transit, and vice versa, and that car transport must be relatively costly in terms of money and/or time, to avoid motorisation.

Curitiba is the seventh largest city in Brazil with population of approximately 1.8 million, and ranks 4th in terms of GDP. Curitiba poses a particular example of how a coherent set of policies can transform a city to an impressive and economic successful example of a low-carbon transportation system. In the 1960s the city adopted and started the implementation of a new urban master plan with the prioritisation of ecological urban structure.

Curitiba's Master Plan integrated transportation with land use planning: commercial growth was encouraged along the arteries radiating out from the city centre – while limiting central area growth. By **developing the city linearly along the arteries**, the downtown ceased to be the primary focus of everyday transport activity. Hence, peak hour commuter congestion was avoided. Also, land within two blocks of the transit arteries is **reserved for high-density development**. New retail growth is channelled to transit stops, and employers offer transportation subsidies for low-skilled and low-paid workers. In contrast, auto-oriented development is not happening, and the downtown centre offers only limited parking, thus discouraging car drivers to clog the city centre with their vehicles. The last (and perhaps most eye-catching) element of Curitiba's development is a **highly efficient bus rapid transit system along the arteries**, effecting a modal shift from car travel to bus travel. Compared to other Brazilian cities of comparable size, Curitibaans consume 30 % less transport fuel.

5. How can a global deal support low-carbon transportation?

In December, 2009 more than 180 heads of state met in Copenhagen in order to negotiate a new climate change agreement. Even if no final agreement has been achieved, Copenhagen is a step towards realizing the principles of the so called Bali Action Plan. In 2007, the climate talks in Bali outlined the basic elements of a new treaty. This includes that developing countries start to reduce greenhouse gas emissions and fight climate change. In return industrialised countries support developing countries in achieving a low-carbon development path. While OECD countries commit to strict and ambitious emission reduction targets, the developing world would contribute to the prevention of a dangerous climate change through mitigation actions. This includes implementing sustainable transport policies.

In Copenhagen, industrialised countries (so called Annex 1 countries as they are listed in Annex 1 of the Kyoto Protocol) committed to provide support in terms of capacity building, technology and finance. Just after the conference in Copenhagen, 36 developing countries submitted so called “Nationally Appropriate Mitigation Actions” (NAMAs). These NAMAs are now listed in Annex II to the Copenhagen Accord¹⁾. Twenty-five of the 36 submissions have made explicit reference to the transport sector, indicating widespread recognition of the role of the sector in climate change mitigation. They also mirror the wider paradigm shift being pursued in the sector, namely to avoid unnecessary journeys, shift travel activity to low carbon modes, and improve the energy efficiency of each mode. NAMA actions proposed have, for

¹⁾ The Copenhagen Accord (Decision CP) was developed at the Climate Change Conference in Copenhagen in December 2009. Since some countries opposed it, the COP only “took note” of the Accord which makes it a non-binding document. It will only gain legitimacy through countries that submit GHG reduction commitments

example, ranged from land-use planning to increasing the energy efficiency of vehicles and fuels and research into the impacts of different strategies.

The main advantage for developing countries in committing to action is *access to support for capacity building, technology transfer and new sources of funding*. During 2010 and the following years the Copenhagen Green Climate Fund or unilateral funds will be developed to match actions and funding needs. All the policies described above are qualified for NAMAs. However, there is one condition that needs to be fulfilled and that is measuring and reporting greenhouse gas reductions of the activities. Hence, many countries have started developing GHG emission baselines (do-nothing scenarios) and carbon foot printing of their policies.

NAMAs will add on to existing carbon finance approaches like the Clean Development Mechanism (CDM) and the transport window of the Global Environmental Facility (GEF). NAMAs seem to be especially a good way forward in supporting developing countries in mitigation strategies. For reductions, not a single policy but a set of integrated measures is required to achieve a decarbonisation of transportation. Low carbon transport strategies are well suited and related to a sustainable transport policy and worth being carefully checked and considered by transport ministries in the coming years.

Box 3

What are Nationally Appropriate Mitigation Actions (NAMAs)?

Nationally Appropriate Mitigation Actions (NAMAs) are voluntary emission reduction measures by developing countries that are directly reported to the United Nations Framework Convention on Climate Change (UNFCCC). NAMAs will be a practical tool in tackling GHG emissions from the transport sector.

- NAMAs are policies, programs and projects that are either economy wide measures (e.g. CO₂ taxation) or specific sectoral initiatives (e.g. fuel efficiency standards).
- NAMAs needs to be submitted to the UNFCCC by national governments but they can include actions on domestic, regional, or local levels.
- NAMAs are an opportunity to acknowledge developing countries' unilateral contribution to reduce GHG emissions and match these with international funding. NAMAs seeking international support will be recorded in a registry along with relevant technology, finance and capacity building support.
